Project Creed Quality Playbook

Quality Assurance (QA) Responsibilities

Quality Assurance (QA) is responsible for establishing architecture and a framework which help avoid introducing defects or bugs at the very initial stages of development.

- Establish testing methodologies and increase the quality standards of the team.
- Employ automatic code checkers in the deployment process in order to avoid any broken code entering the live server environment.
- Collaborate with system architects in order to develop services and databases which are testable and observable.
- Analyze patterns of failures occurred in previous development cycles in order to provide better guidelines on coding and avoid making architectural mistakes.

Quality Control (QC) Responsibilities

The responsibility of Quality Control (QC) is to catch the flaws/bugs in the existing software before any actual user encounters them.

- Perform checks on each and every feature to ensure that the software functions as per its intended design.
- Click around randomly, test with unusual inputs, and go beyond the boundaries where the application starts behaving abnormally.
- Reproduce functional defects, capture logs of the bug and document the issue in the issue tracking system.
- Go through system error handling, responsiveness of UI, and compatibility matrices in the targeted client environment.

Our Guiding Principles

Exhausting Testing is Impossible: It’s impossible to test all possible combinations of buttons or all possible edge cases; there simply is not enough time for that. We concentrate on functionality that can potentially cause harm to the business if it fails. Team deals with this problem on a daily basis by applying risk-based testing approach.

The Pesticide Paradox: Repeatedly applying the same test scenario will no longer reveal defects at some point because both the code and the developer adapt to the tests. In order to overcome the problem on a daily basis, test cases should be constantly refreshed, new data should be used to run tests, and testers should test features freely.

Absence-of-Errors Fallacy: The lack of errors does not guarantee that the feature will please its users because it can either be hard to understand or solve a wrong problem. Quality means actual usefulness of the application. Teams deal with this problem on a daily basis by linking quality testing and product validation.
